

② if let  $L$  be a <sup>infinite</sup> Turing recognizable language.  
If  $L$  is T-recognizable, there must a enumerator  
for it. Let that enumerator be  $E$ .

~~Let's const~~

A enumerator  $E'$  exists that runs  $E$  and prints  
only those strings in  $E$  that are printed by  $E$   
that are longer than, previous string printed  
by  $E'$ .

$E'$  ~~consis~~ prints those strings that belong to  $L$ .  
 $E'$  is an enumerator for  $L$ . ~~However~~

A TM  $D$  exists that runs  $E'$ . If any string printed  
by  $E'$  matches the input string then accept.  
If any string printed by  $E'$  is longer than input  
string; reject. Since, all shorter strings have  
been already printed, this implies ~~that~~ ~~the~~  
~~that~~ input string doesn't belong to  $D(L)$ .

$D$  is a decider and it only accepts strings  
that belong to  $L$ .

Therefore,  $D(L)$  is a decidable subset for  $L$ .

Hence, every infinite Turing recognizable language  
has a Turing decidable subset.
